3.1 introduction to signal and system

3.1.1 preface

While students studying signals and systems should certainly have a solid foundation in disciplines based on the laws of physics, they must also have a solid foundation in disciplines based on the laws of physics, they must also have a firm grounding in the use of computers for the analysis of phenomena and the implementation of systems and algorithms. As a consequence, engineering curricula now reflect a blend of subjects, some involving continuous-time models and others focusing on the use of computers and discrete representations. For these reasons, signals and systems courses that bring discrete-time and continuous-time concepts together in a unified way play an increasingly important role in the education of engineering students and in their preparation for current and future developments in their chosen fields.

It has pedagogical advantage by taking both the continuous-time and discrete-time in mind.

Chapter 1 introduces block diagram representations of interconnections of systems and discusses several basic system properties such as causality, linearity and time-invariance.

The concepts of signals and systems arise in a wide variety of fields, and the ideas and techniques associated with these concepts play an important role in such diverse areas of science and technology such communications, aeronautics and astronautics, circuit design, acoustics, seismology, biomedical engineering, energy generation and distribution systems, chemical process control, and speech processing. Because of its importance, it worth to take time to digest each single idea and concept appearing in such course. Also, it will be greatly helpful for the newbie to have an open course to help them dive into the world of signals and systems. I tried my best to give the best explanation of the concept in this course and

comprehensive details are given during my creation of videos and posts. It takes time to produce one piece of work so that sometimes I think it was a grind. However, for the sake of beautiful result, I pretty enjoy the process of doing such creation.

The signals, which are functions of one or more independent variables, contains information about the behavior or nature of some phenomenon, whereas the systems respond to particular signals by producing other signals or some desired behavior.

Examples:

1. Voltages and currents as a function of time in an electrical circuit are examples of signals. and a circuit is itself an example of a system, which in this case responds to applied voltages and currents.
2. As another example, when an automobile driver depresses the accelerator pedal, the automobile responds by increasing the speed of the vehicle.
3. A computer program for the automated diagnosis of electrocardiograms can be viewed as a system which has as its input a digitized electrocardiogram and which produces estimates of parameters such as heart rate as outputs.
4. A camera is a system that receives light from different sources and reflected from objects and produces a photograph.
5. A robot arm is a system whose movements are the response to control inputs.

The purpose of signals and systems:

1. characterizing the system in detail to understand how it will respond to various inputs.
2. design systems to process signals in particular ways. such enhancement and restoration of certain signals, extraction of specific pieces of information from signals.
3. modify or control the characteristics of a given system.

3.1.3 definition of signals and systems

A signal is defined as any physical quantity that varies with time, space, or any other independent variable or variables. Mathematically, we describe a signal as a function of one or more independent variables. Signals convey information.

A continuous-time signal is a quantity of interest that depends on an independent variable, where we usually think of the independent variable as time. In the real world, physical quantities take on real numerical values, though it turns out that sometimes it is mathematically convenient to consider *complex-valued functions of t* . However, the default is real-valued $x(t)$, and indeed the type of sketch exhibited about is valid only for real-valued signals.

Remarks:

1. A continuous-time signal is not necessarily a continuous function as defined in calculus. They are two different definition.
2. The independent variable need not to be time, it could has other meaning. But considering it as time does not affect we study the concepts of signals and systems.

A discrete-time signal is a sequence of values of interest, where the integer index can be thought of as a time index, and the values in the sequence represent some physical quantity of interest. Because many discrete-time signals arise as equally-spaced samples of a continuous-time signal, it is often more convenient to think of the index as the "sample number".

Systems process signals to produce a modified or transformed version of the original signal. For the information and communication technology, signals and systems helps engineer to analyze and design the signals and systems they meet in daily life.

3.1.4 summary of chapter 1

We developed a number of basic concepts related to continuous-time and discrete-time signals and systems. We have presented both an intuitive picture of what signals and systems are through several examples and a mathematical representation for signals and systems that we will use throughout the book. Specifically, we introduced graphical and mathematical representation of signals and used these representations in performing transformations of the independent variable. We also defined and examined several basic signals, both in continuous time and in discrete time. These included complex exponential signals, sinusoidal signals, and unit impulse and step functions. In addition, we investigated the concept of periodicity for continuous-time and discrete-time signals.

In developing some of the elementary ideas related to systems, we introduced block diagrams to facilitate our discussions concerning the interconnection of systems, and we defined a number of important properties of systems, including causality, stability, time-invariance, and linearity.

The primary focus in most of this book will be on the class of LTI systems, both in continuous time and discrete time. These systems play a particularly important role in system analysis and design, in part due to the fact that many systems encountered in nature can be successfully modeled as linear and time invariant. Furthermore, as we shall see in the following chapters, the properties of linearity and time invariance allows us to analyze in detail the behavior of LTI systems.

They comprehensively cover both classical Fourier techniques and newer basis constructions from filter banks and multiresolution analysiswavelets. Furthermore, they gives a synthetic view from basic mathematical principles, to construction of bases, all the way to concrete applications.

With a novel, less formal approach to the subject, the authors have written a book with the conviction that signal processing should be taught to be fun. The treatment is less focused on the mathematics and more on the conceptual and practical aspects but the book remains an engineering text, with the goal of helping students solve real-world problems. In this vein, the last chapter pulls together all the topics discussed throughout the book into an in-depth look at the development of an end-to-end communication system, namely, a modem for communicating digital information over an analog channel.

Signals convey information. Systems transform signals. This book introduces the mathematical models used to design and understand both. It is intended for students interested in developing a deep understanding of how to digitally create and manipulate signals to measure and control the physical world and to enhance human ex-

perience and communication. This book is based on several years of successful classroom use at the University of California, Berkeley. The material starts with an early introduction to applications, well before students have built up enough theory to fully analyze the applications. This motivates students to learn the theory and allows students to master signals and systems at the sophomore level. The material motivates signals and systems through sound and images. Calculus is the only prerequisite.
